

Sun Angle and Solar Energy Transfer

Real-World vs. Experimental Data Analysis

Last week each group developed a hypothesis relating sun angle to temperature and then devised an experiment to test these hypotheses. Your lab reports should contain the procedures and results of your experiment and the preliminary analysis you derived from your experimental data.

Today we will go beyond your original experimental data and use real data gathered from temperature datasets from NOAA and other sources. Additionally, new analytical techniques will be used to help better quantify the actual solar intensity at our test sites.

Upon the conclusion of these calculations student groups will revisit their preliminary analyses and:

1. Determine if their original analysis reflected similar results as those from the real-world data and,
2. Revise their analysis to include new test results and techniques learned in today's lab.

When you have completed the calculations and final analyses, please enter these into your lab report.

As with the preliminary analysis, you should have all lab group members review and amend the lab report to reflect all group members ideas and contributions. Please note that there may be different interpretations within the group when it comes to the final analysis portion. If this is the case it would be best to include all differing analyses and the reasoning behind them. Please note which members are aligned with each analysis.

You should now turn in your group lab report and be sure that all group members full names are shown on the cover. This will conclude the group portion of this lab.

A discussion question will be posted and everyone is required to write an individual and original response to this/these question(s). Once your initial response has been received, you will then be able to read and comment on the postings of your fellow students. You will be required to engage in an online discussion of these comments with at least 3 other students. The deadlines for your original post and your online discussion will be explained during lab.

Calculating Solar Intensity

Your understanding of sun angle and its impact on the earth's surface is a good first step in understanding how the sun's energy affects the planet. We will now go into more depth as we seek to understand quantifiably this impact.

The main reason why certain areas on Earth are warmer than other areas is because they receive a greater intensity of solar radiation, which is directly related to the sun angle. Sun angle (also called

altitude angle) is very important because it affects the intensity of solar radiation reaching the ground. When sun angles are large (i.e. closer to 90°) solar rays are more direct and deliver more energy. As sun angle decreases, radiation is spread over a larger surface area. When more surface area “shares” the solar energy, the intensity of the energy received is less. Figure 3.5 illustrates this idea by comparing the surface area of radiation for sun angles of 70° and 36.5°. The surface area of radiation for the higher sun angle is less than for the lower sun angle, meaning that the higher the sun angle, the more intense the radiation is at the surface.

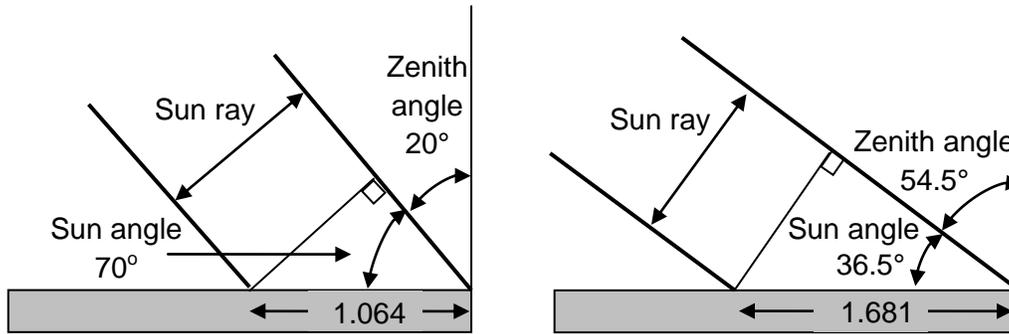

Fig. 3.5 Solar Angle and Surface Area

Surface Area of Radiation. The surface area that the sun’s ray covers changes with the sun angle and can be determined through trigonometry. The following equations are used to determine the surface area:

$$\sin(\angle A) = \frac{1 \text{ unit width}}{\text{surface area}} \quad \text{and} \quad \text{surface area} = \frac{1}{\sin(\angle A)}$$

For example, if the altitude angle = 50° then

$$\text{surface area} = \frac{1}{\sin(50^\circ)} = \frac{1}{0.766} = 1.305;$$

this means that 1 unit area of sunshine striking the earth with an altitude angle of 50° will be spread over an area of 1.305 (i.e. an area 30.5% larger).

Percentage of Beam Intensity. As solar radiation is spread over more of the Earth’s surface, the intensity of the beam decreases according to the following equation:

$$\text{percent of beam intensity} = \sin(\angle A) \times 100$$

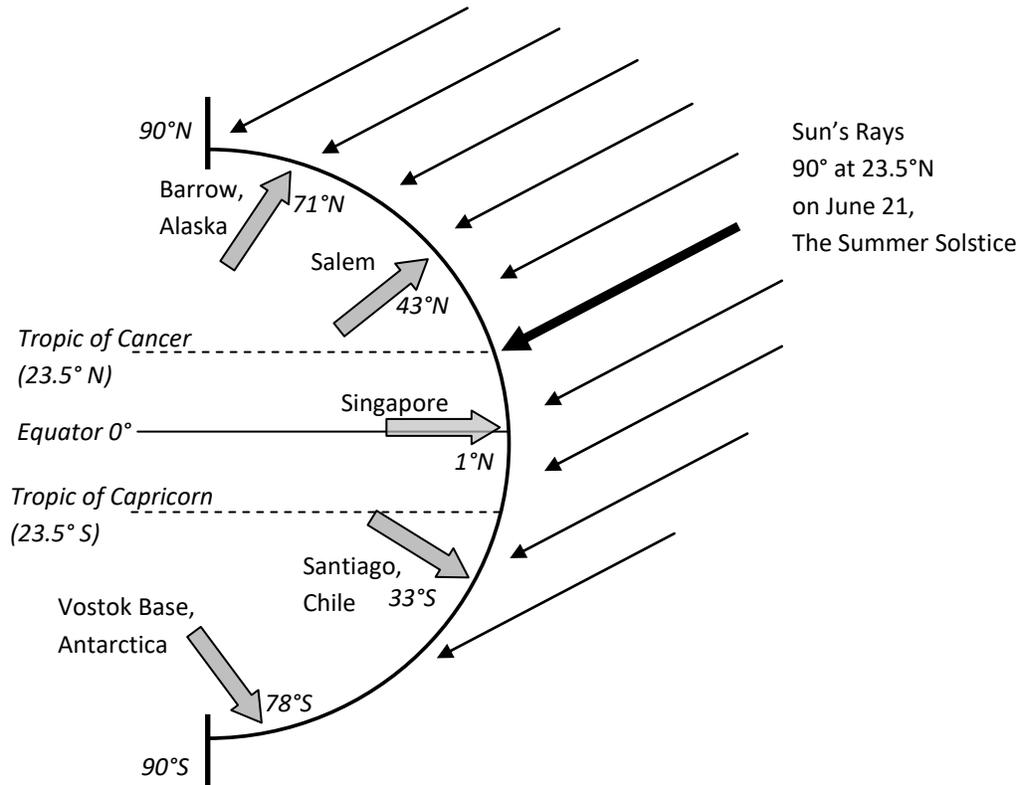

For example, if the altitude angle = 50° then:

$$\sin(50^\circ) = 0.766 \times 100 = 76.6 \quad \text{or} \quad 76.6\%.$$

Surface Area of Radiation and Beam Intensity Exercises

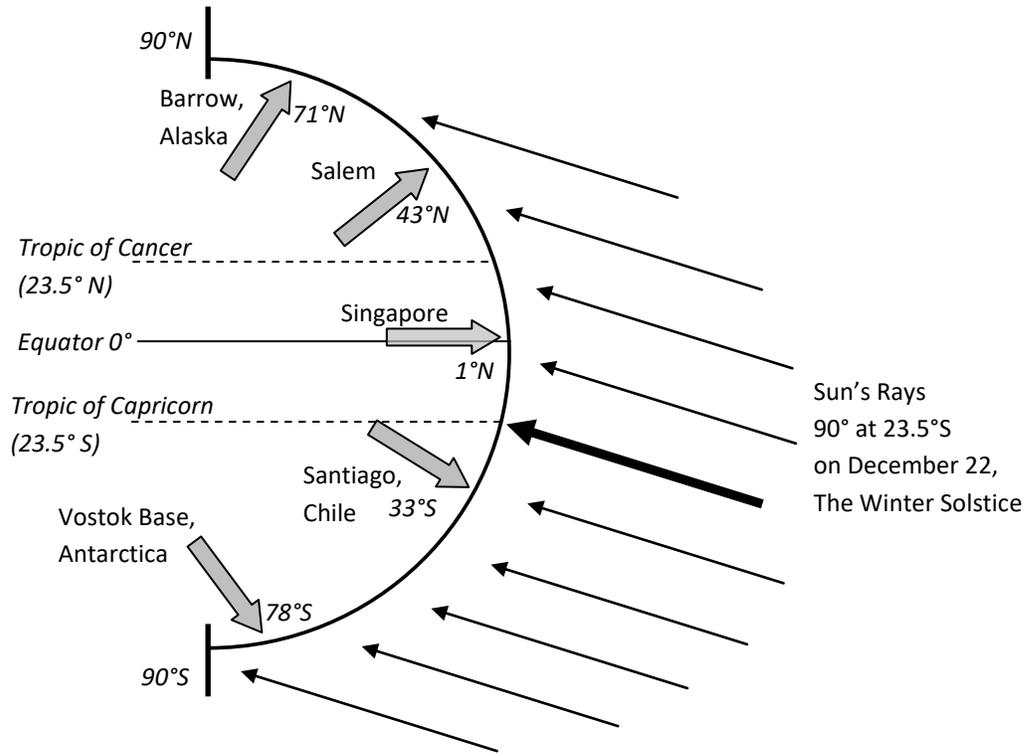

Calculate the Surface Area of Radiation (SAR) and Beam Intensity (BI%) for the following locations on the dates specified.

The Summer Solstice, June 21

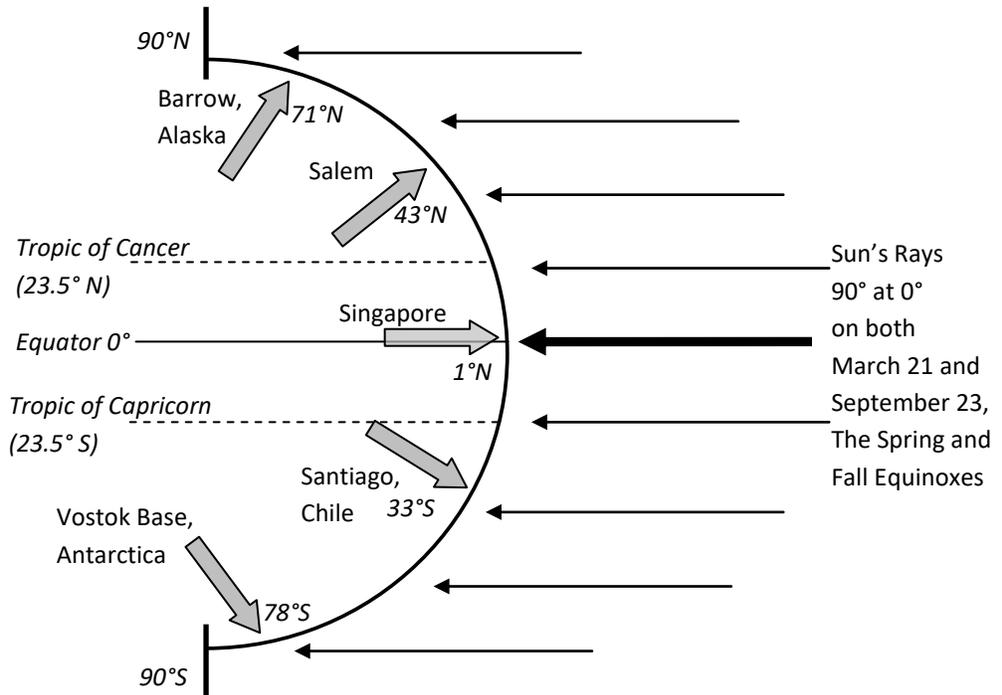

| Place | Lat of Place | Lat. Of 90° Sun | Ang. Dist / Zenith Ang. | Sun Ang. | SAR | BI% |
|-------------------------|--------------|-----------------|-------------------------|----------|-----|-----|
| Barrow, AK | 71° N | 23.5° N | | | | |
| Salem, MA | 43° N | 23.5° N | | | | |
| Singapore | 1° N | 23.5° N | | | | |
| Santiago, Chile | 33° S | 23.5° N | | | | |
| Vostok Base, Antarctica | 78° S | 23.5° N | | | | |

The Winter Solstice, December 21

| Place | Lat of Place | Lat. Of 90° Sun | Ang. Dist / Zenith Ang. | Sun Ang. | SAR | BI% |
|-------------------------|--------------|-----------------|-------------------------|----------|-----|-----|
| Barrow, AK | 71° N | 23.5° S | | | | |
| Salem, MA | 43° N | 23.5° S | | | | |
| Singapore | 1° N | 23.5° S | | | | |
| Santiago, Chile | 33° S | 23.5° S | | | | |
| Vostok Base, Antarctica | 78° S | 23.5° S | | | | |

The Spring Equinox (March 21) and the Fall Equinox (September 23)

| Place | Lat of Place | Lat. Of 90° Sun | Ang. Dist / Zenith Ang. | Sun Ang. | SAR | BI% |
|-------------------------|--------------|-----------------|-------------------------|----------|-----|-----|
| Barrow, AK | 71° N | 0° | | | | |
| Salem, MA | 43° N | 0° | | | | |
| Singapore | 1° N | 0° | | | | |
| Santiago, Chile | 33° S | 0° | | | | |
| Vostok Base, Antarctica | 78° S | 0° | | | | |

Sine Table:

| Angle | Sin θ |
|-------|--------------|-------|--------------|-------|--------------|-------|--------------|
